

ELISA KIT CATALOG

WELCOME

Proteintech sandwich ELISA kits provide a simple and elegant solution for your immunoassay needs. The procedure is straightforward and allows you to detect and quantify your target protein, reliably and accurately, in a range of biological samples in the space of a morning or afternoon. Proteintech's ELISA kits are based on the two-site sandwich immunoassay principle, in which two highly specific, non-competitive antibodies are used in the detection of a target analyte: one for capture, and one for detection.

Each Proteintech sandwich ELISA kit has been rigorously assessed for intra- and inter-assay variability and data show high levels of assay consistency and sample recovery (provided with every datasheet). The development of a typical Proteintech sandwich ELISA kit is reviewed in the next section. Briefly, steps involved in making Proteintech's sandwich ELISA kits include:

- Careful selection of antibody pairs to ensure optimum signal
- Calibration with NIBSC/WHO Standards
- Testing with multiple sample types, e.g., sera, plasma, cell culture supernatant
- Testing of intra- and inter-assay precision
- Linearity testing
- Recovery testing
- Kit stability testing

WHAT GOES INTO MANUFACTURING A PROTEINTECH ELISA KIT?

Antibody Selection

The antibody selection procedure identifies the best detection and capture antibodies for pairing together in a sandwich ELISA immunoassay. The ideal capture antibody must possess high sensitivity and affinity toward the target antigen to perform its function in an ELISA experiment. For this reason, polyclonal antibodies, raised against large segments or all of the target protein, are first explored in the selection process*. A high antibody titer in an indirect ELISA experiment identifies the most suitable candidate.

Suitable detection antibodies must be tested for their specificity and, most importantly, compatibility with a capture antibody. Because of their high specificity, consistency, and reproducibility, monoclonal antibodies are utilized for the detection stage of a sandwich ELISA experiment. On average, 10 monoclonal subclones are assessed in the antibody selection process. Antibodies from each subclone are evaluated for compatibility with the capture antibody. The best detection antibody gives a strong and reliable signal that is consistent across multiple rounds of testing and dilutions of the protein target. Its signal should not be affected by antigen binding to the capture antibody, i.e., their binding sites should not compete or overlap.

The majority of our antibodies are raised against whole-protein immunogens, which means expressing a large section of the target protein, or even all of it where possible, and introducing this to the host immune system as the antigen. Our standard 102-day-long immunisation protocol paired with whole-protein antigens allows several things to happen in the host immune system that contribute to superior antibodies:

- **Selection of sites with greater immunogenicity by major histocompatibility complex (MHC) class II molecules.**
- **Affinity maturation in peripheral lymphatic tissues.**
- **Mounting of a secondary immune response that produces antibodies with greater recognition capabilities.**

Calibration

Our protein standards are calibrated using World Health Organization (WHO) Expert Committee on Biological Standardization (ECBS)-approved standards, sourced from The National Institute for Biological Standards and Control (NIBSC).

The Proteintech lab also measures the coefficient of variation of its kits against the equivalent NIBSC standard to test the inter-assay variability from one use to the next (typically, several experiments will be carried out over a few days to assess inter-assay variability). Intra-assay variation is also tested, i.e., variability between duplicates, and is done for every separate batch of each individual ELISA kit made.

Rigorous Testing

All Proteintech ELISA kits are assessed for their recovery, linearity, range, sensitivity, and stability indices.

"On average, 10 monoclonal subclones are assessed in the antibody selection process. Antibodies from each subclone are evaluated for compatibility with the capture antibody."

“The dynamic range, i.e., the upper and lower detection limits, of each kit is assessed using a series of dilutions over several replicates.”

Recovery

The recovery index is a measure of how an assay is affected by the sample medium being used, e.g., serum or plasma. A known amount of a protein standard, usually a fusion protein of the target, is combined with the experimental medium and subjected to the sandwich ELISA procedure. This procedure is known as “spike recovery.”

The lab performs spike recovery experiments with three concentrations considered: “Low,” “medium,” and “high” (e.g., low = 50 pg, medium = 500 pg, and high = 2000 pg). Each is done several times with different sample types: serum, urine, plasma, cell culture supernatant. The output of each spike is then measured against a standard prepared in sample diluent. The ratio of sample output to diluent control output is expressed as a percentage, referred to as the recovery index. A recovery index of 80-120% is considered desirable.

Linearity and Range

The linearity index of an ELISA kit indicates the precision of assay results for samples tested at different levels of dilution in the chosen sample diluent. Where a sample medium already contains the endogenous target, the Proteintech lab tests linearity directly (by performing series dilutions of the medium). If a medium carrying endogenous sample cannot be obtained, a similar procedure to spike recovery is performed (i.e., a known amount of protein is added to a sample before dilution is performed). Typically, linearity is measured over serial 2-fold dilutions.

The dynamic range, i.e., the upper and lower detection limits, of each kit is assessed using a series of dilutions over several replicates. Providing this data helps kit users to optimize their dilution range when designing or revising their assays.

Sensitivity

Sensitivity assays are carried out on each prototype ELISA kit to assess baseline signal, i.e., the threshold of minimum detection. If your sample data is higher than the sensitivity readout, the sample may be considered positive; if lower than the sensitivity readout, the sample is negative and the data should be discarded.

Sensitivity is determined by performing the ELISA procedure with multiple negative samples. The OD readouts of each negative sample are averaged out and the standard deviation calculated. Sensitivity is then calculated using the formula:

$$\text{Average} + (\text{STDEV} \times 2) = \text{XOD}$$

XOD is then read from the standard curve of the linearity experiment.

Stability

Proteintech tests all its ELISA kits following reagent incubation at 37°C after both three and five days. It also tests them after 45 days' storage at 4°C. Only those kits with no loss of performance are approved for sale.

**It may not always be the case that a polyclonal antibody is the best for protein capture, and this is also taken into consideration during kit design.*

THE BENCHMARK IN ANTIBODIES

Since the day it was founded, Proteintech has been making all of its products to the highest standards possible whilst taking complete responsibility for the quality of each product.

- Proteintech makes every single antibody in its 12,000+ catalog.
- Each Proteintech product is unique and cannot be bought under a different label.
- Antibodies are tested with siRNA treated samples to demonstrate specificity.
- It works in every single species and application or get a full money-back refund.

Proteintech has over 12,000 antibodies in its extensive catalog, all fully validated and available for next day delivery.
